

Building a Better Moat

Designing an Effective
Covert Red Team
Attack Infrastructure

Agenda

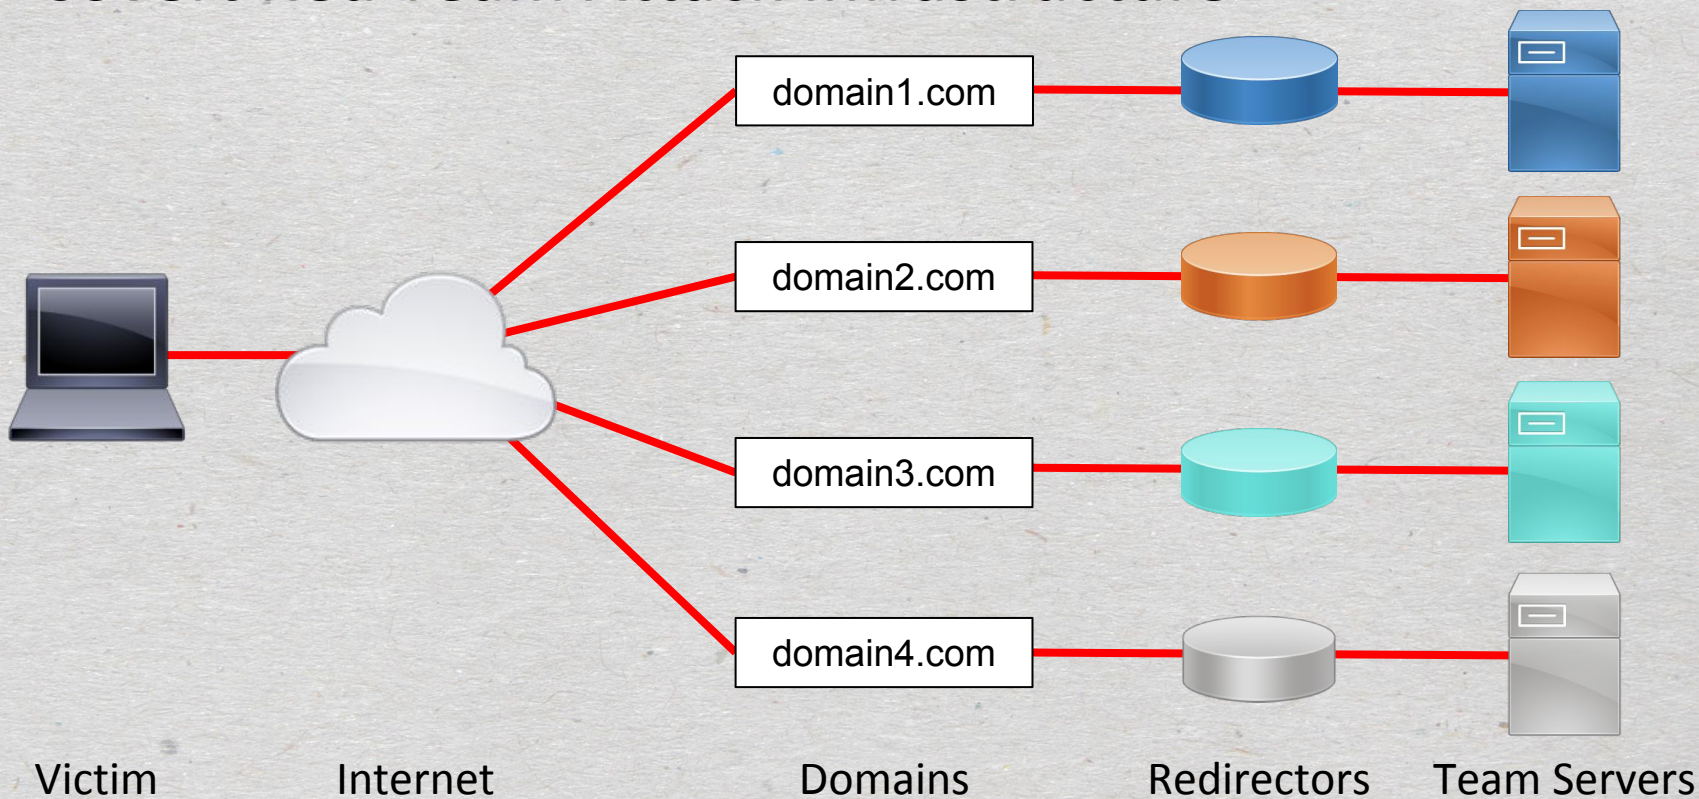

- Introduction
- Design Considerations
 - General
 - Domains
 - Payloads
 - C2
 - SMTP
- Example Infrastructure Designs
- Key Takeaways

What is a Covert Red Team
Attack Infrastructure?

Standard Pentest Setup

Covert Red Team Attack Infrastructure

Benefits of a Covert Infrastructure

- Blends in with non-malicious infrastructure
- Builds in defenses against Blue team
- Resilience when an asset is blocked
- Flexibility to adapt as the test progresses

Design Considerations

Design Considerations - General

- Segregate all assets based on function
- Place a redirector in front of every asset
- Blend in with normal traffic for the target
- Configure assets in a way that individual pieces can be rolled
- Keep the length of the test in mind when designing

Design Considerations - General

- Don't go overboard for your target
- Tailor the design for anticipated or encountered obstacles
- Evaluate infrastructure primitives before choosing one
- Be fluid as the test goes; redesign as needed

(Sidenote: document EVERYTHING)

Design Considerations - Domains

- Always use categorized domains*
- Pre-categorized vs. home-grown
- Matching the target's domain categorization can help blend in
- Alternatively, organizations often have domain category whitelists (try Healthcare/Finance!)

*unless emulating an actor who doesn't

Design Considerations - Domains

- Domains should match planned pretext
- Good choices:
 - Impersonate target company
 - Similar to popular companies/services (Google, Microsoft, etc.)*
 - Generalized domains that match industry

*There are precedents for companies coming after squatters

Design Considerations - Payloads

- Payload type
 - HTA, LNK, PowerShell download cradle, etc
- Delivery method (attached, web-based)
 - Attachment
 - Download link (server vs. cloud storage)
- Access control options
 - IP/fingerprint-based restrictions
 - Expiring payload links

Design Considerations - Payload Redirection

- “Dumb pipe”
 - socat/iptables
 - Forwards all connections
 - No monitoring of requests
- Filtering
 - Apache mod_rewrite, nginx
 - Perform conditional processing on requests
 - Modify rulesets on the fly

Design Considerations - Command and Control (C2)

- Longhaul
 - Used to regain access
 - Persistence
 - Slow check-ins
- Shorthaul
 - Used for primary operating
 - Burned frequently
 - Faster check-ins
- Number of servers

Design Considerations - Command and Control (C2)

- Popular protocol choices:
 - HTTP(S)
 - DNS
 - Domain Fronting (over HTTPS)
 - Third-party

Design Considerations - Command and Control (C2)

| <i>Attribute</i> | HTTP(S) | DNS | Domain Fronting | Third-Party |
|---------------------------|----------------|------------|------------------------|--------------------|
| <i>Latency</i> | Low | High | Medium | Medium |
| <i>Likelihood to Work</i> | Average | High | High | High |
| <i>Detectability</i> | Average | High | Low | Low |
| <i>Ease of Blocking</i> | Average | Low | Low | Low |
| <i>Ease of Setup</i> | Easiest | Easy | Medium | Medium/Hard |

Design Considerations - Command and Control (C2)

- Traffic shaping:
 - Custom network footprint
 - Emulate a specific application or threat actor
 - Modify potential signatures (URIs, user agents, etc.)
 - Modify any host implant attributes as much as possible
- Use custom profiles for each server

Design Considerations - Command and Control (C2)

- Choose an appropriate protocol and redirection method per server
 - Validate latency before launching the test
- Keep servers separate
 - Shorthaul and longhaul servers fulfill different roles
 - Be disciplined with each server type
 - Never cross the streams!
- Don't be afraid to roll new infrastructure

Design Considerations - C2 Redirection

- “Dumb pipe”
 - Easiest setup, no filtering protections
- Filtering
 - Longer setup, higher resilience
- Domain Fronting/Third-Party C2
 - Requires setup or development
 - Blends in well
 - Very hard to block

Design Considerations - SMTP

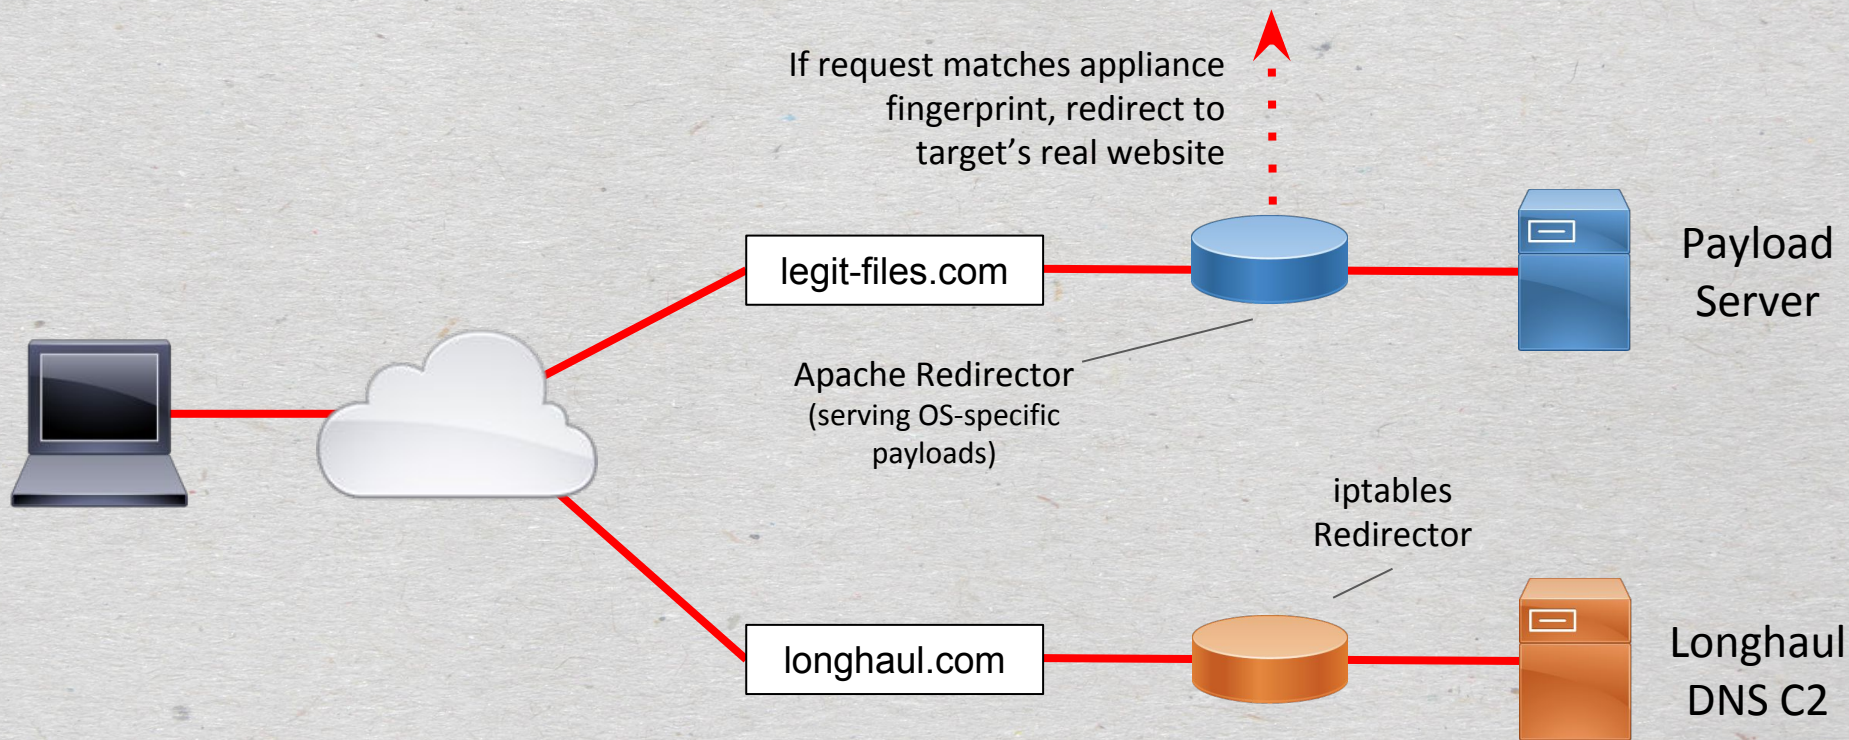

- Self-setup
 - Set up yourself
 - DKIM, SPF, PTR records needed
 - Can be time-intensive
- Third-party
 - Automatic reputation
 - Anti-spam controls
- Open Relay
 - Can use target's own server against them
 - Anti-spam controls could get you flagged

Example Infrastructure Designs

Example Infrastructure Design #1

- Email attachments blocked
- Pre-phish revealed email appliances
- Appliances crawl all links in emails
- No intel about web browsing restrictions
- Mixed OS environment

Example Infrastructure Design #1

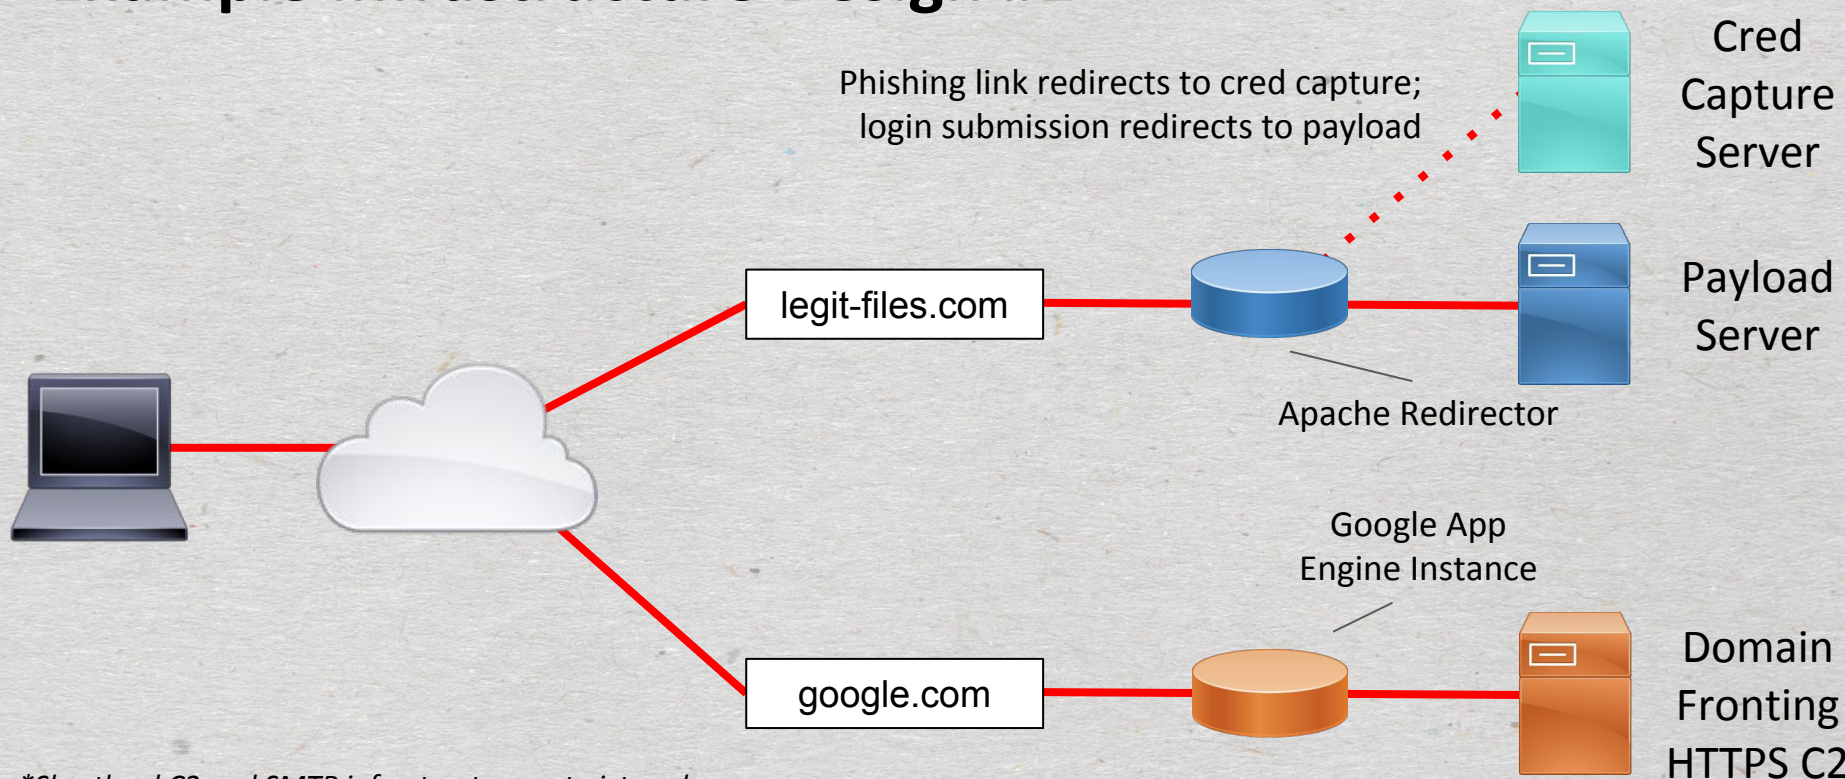

**Shorthaul C2 and SMTP infrastructure not pictured*

Example Infrastructure Design #2

- About half of users don't have internet access
- Those with internet access are heavily restricted
- Publicly-accessible OWA and remote access logins

Example Infrastructure Design #2

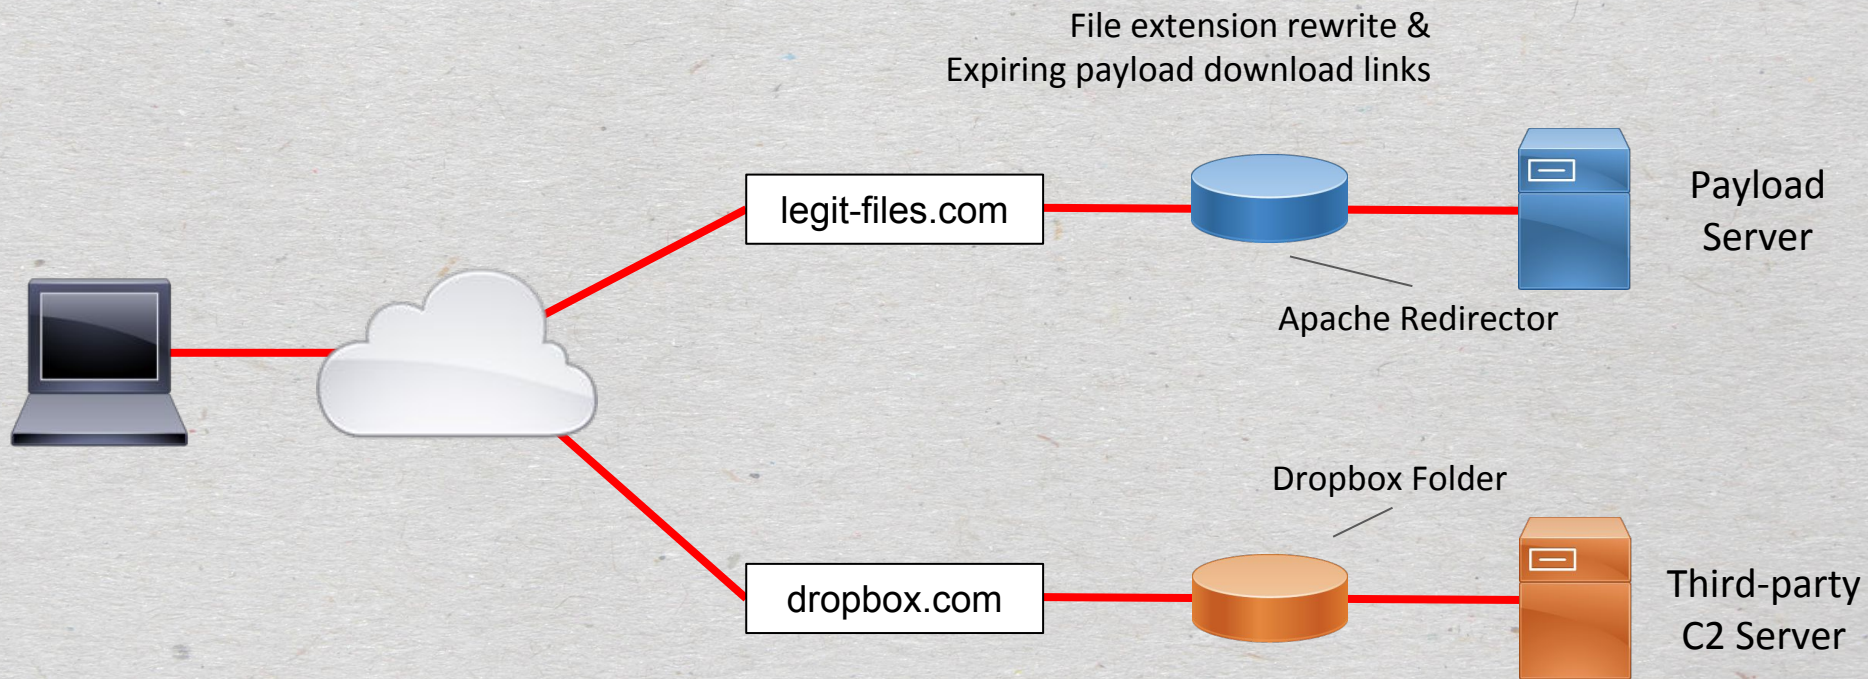

**Shorthaul C2 and SMTP infrastructure not pictured*

Example Infrastructure Design #3

- Email attachments blocked
- Email appliance reviews all links and blocks wide range of file extensions
 - docx allowed
- Pre-phishing was manually acted on quickly
- Found case study for the target's deployment of a popular online storage service

Example Infrastructure Design #3

**Shorthaul C2 and SMTP infrastructure not pictured*

Key Takeaways

- Segregate assets
- Use redirectors, ideally with filtering
- Stress test assets for operational latency
- Document EVERYTHING
- Don't go overboard - achieve your objectives
